1. Project Requirements Overview

Mandatory Requirements

- **Virtual Machine:** All work must be done in a VM
- **Docker Compose:** Use docker-compose.yml for orchestration
- **Custom Dockerfiles:** No pulling ready-made images (except Alpine/Debian base)
- **Three Core Services:**
 - NGINX with TLSv1.2/1.3 only
 - WordPress + PHP-FPM (without nginx)
 - MariaDB (without nginx)
- **Infrastructure Components:**
 - Two volumes (database + website files)
 - Custom Docker network
 - Automatic restart on crash
- **Security Requirements:**
 - No passwords in Dockerfiles
 - Use environment variables
 - Implement Docker secrets
 - NGINX as only entry point via port 443

Key Restrictions

- No `network: host` or `--link`
 - No infinite loops (`tail -f`, `sleep infinity`, etc.)
 - No `latest` tag usage
 - Domain must be `login.42.fr`
 - Database users: admin user cannot contain "admin" or "administrator"
-

2. Docker Fundamentals

What is Docker?

Docker is a containerization platform that packages applications and their dependencies into lightweight, portable containers. Unlike virtual machines, containers share the host OS kernel.

Key Concepts

Images vs Containers

- **Image:** Read-only template with application code and dependencies
- **Container:** Running instance of an image
- **Layer:** Each instruction in Dockerfile creates a new layer

Container Lifecycle

Docker Image → Docker Container → Running Process

Docker Architecture

- **Docker Daemon:** Background service managing containers
- **Docker Client:** Command-line interface
- **Docker Registry:** Storage for Docker images (DockerHub)

Essential Commands

```
bash
```

```
# Image management
```

```
docker build -t name:tag .
```

```
docker
```
